

Room to Grow

Story

PyConES 2026 is getting bigger.

Much bigger.

The organising team has started preparing the conference rooms, but there is a small problem: every time a room reaches its maximum capacity, the team can **double** the number of available seats.

The first room starts with **1 seat**.

After one expansion, it has 2 seats.

After two expansions, it has 4 seats.

After three expansions, it has 8 seats.

And so on...

One of the organisers looks at the spreadsheet and says:

"We have the number of expansions, but nobody calculated the final capacity!"

Another person opens their Python editor.

"Don't worry. This sounds like a job for Python."

Your task is to calculate how many seats the room will have after a given number of expansions.

Problem Statement

Given an integer n , calculate the number of seats available after performing n expansions.

The room starts with **1 seat**, and each expansion **doubles** its capacity.

Input Format

A single line containing an integer:

n

Constraints

- $0 \leq n \leq 30$

Output Format

A single integer representing the number of seats available after n expansions.
