

Story

PyConES 2026 has finally begun! Everyone is talking, meeting new people, and sharing their love for Python. You can almost smell Python in the air.

The organizers have a brilliant idea: they want to know **how many times the word Python is mentioned** during the conference.

So they start counting:

- One time.
- Two times.
- One hundred times.
- One thousand nine hundred and ninety-nine times...

Wait... there are too many! They will never finish counting them all by hand.

One of the organizers has an idea:

"We need a Python program to count them for us!"

The computer is ready. The editor is open. It's time to write some code.

Problem Statement

Given a string, count how many times the word Python appears in it.

The word must be counted only when it appears exactly as Python, with the same capitalization.

Input Format

A single line containing a string.

Constraints

- The string contains between **1 and 100,000 characters**.
- The string contains only **English letters** and spaces.
- The word Python may appear zero or more times.

Output Format

A single integer with the number of times Python appears in the string.
